STAT

HAULING OF FERROUS METALS ON USSR RAILROADS

Hauling Characteristics

In the freight turr ver of the USSR railroad systems, ferrous metals amount to 5 percent of the ton...e and 7.4 percent of the ton-kilometrage (1947 figures). In 1950, the hauling of ferrous metals should increase 40 percent over 1940.

The average length of haul of ferrous metals on the railroads of the USSR amounted to:

1928 786
1932 914
1940 966
1946 1,240
1947 1,120

The average length of haul for different types of ferrous metals varies greatly. In 1947, when the average length of haul of ferrous metals was 1,120 kilometers, crude iron and steel were hauled 966 kilometers, pig iron 950 kilometers, rail 1,234 kilometers, and other rolled products 1,414 kilometers.

In the over-all hauling of Terrous metals by the railroads, the hauling of pig iron amounts to about 30 percent, ingots 5 percent, and rolled products and pipe 65 percent.

The burdening of the railfoad lines by the hauling of ferrous metals and the freight flow of ferrous metals depends not only on the geographical distribution of the rolling mills but also on their specialization in the production of specific types of rolled articles. The correct specialization of the rolling mills, taking into consideration the requirements for the various types of metals by regions of consumption requiring them, is of great significance in determining the effective flow of ferrous metals on the railroads.

Planning of Ferrous Metal Carrying

The planning of ferrous metal carrying at present is concentrated in the ministries producing ferrous metals. The main suppliers of ferrous metals are the Ministry of Metallurgical Industry and, to a certain extent, the smaller metallurgical enterprises under the management of the Ministries of Transport Machine Building, Armaments, and Shipbuilding Industry. The supply of ferrous metals produced by the small metallurgical enterprises is done on order of the Main Administration of Metal Sales of the Ministry of Metallurgical Industry.

Car norms for loading ferrous metals are determined by the ministries which supply ferrous metals and also by the economic ministries which distribute the ferrous metals among its enterprises. Guided by a government-approved plan for the distribution of ferrous metals, the consumer ministries submit orders on the allocated stocks to the Main Administration of Metal Sales of the Ministry of Metallurgical Industry, with instructions as to the standard shapes, sizes, and types of metals required. The Main Administration of Metal Sales of the Ministry of Metallurgical Industry then assigns the consumers to the plant producers on the basis of establishing the special needs of the consumer ministries and on the basis of plans for the production of ferrous metals. The Main Administration of Metal Sales distributes the orders for metal to the metallurgical plants. All necessary specifications pertaining to dimensions of the rolled products are worked out directly among the plant suppliers and the consumers.

The normal pattern of flow of various types of rolled products via the railroads, developed with regard to the specialization of the rolling mills, must be the main guide for distributing orders to the metallurgical plants for the supplying of specific types of rolled products to definite consumers. Because of the radical relocation of metal consumers in the country's various economic regions during the war and postwar period and also because of the relocation of metallurgical production, new specialties were assigned to rolling mills according to government decrees. This has a considerable influence on the efficient hauling of metals.

The issuance of orders to metallurgical plants is an important part of planning the haul g of ferrous metals. On the basis of orders by the Main Administration of Metal Sales, the Ministry of Metallurgical Industry compiles a quarter loading plan according to railroad systems of origin and destination and this is presented, together with the hauling plan, for government approval. The supplier ministries, on the basis of the above plan and also on the basis of orders for metal supply, present to the railroad systems' managements a similar hauling plan according to stations and railroad systems of origin and destination.

In distributing orders to the plants supplying ferrous metals there ensues the problem of obtaining the maximum transit shipping from the producer plants directly to the consumers.

However, it is not always possible to completely supply metal in transit consignments. While consumer ministries usually ship metal to their plants in large carload consignments, they often are forced to distribute to their consumers special shapes and types of rolled products (produced in special metal-lurgical plants) in small consignments, which precludes the possibility of shipping them in carload lots. In these cases, the small consumers receive the required metal from the regional bases of the Main Administration of Natural Sales.

When shipping small lots of special shapes, the metal from the plant producers is gathered together for several consumers and then sent to the regional bases. At the regional bases the metal from several plants is collected in carload lots of various shapes, sizes, and types of metal for specific consumers. A second unloading of the metal is carried out at these bases. In such cases, the reshipping permits a greater utilization of the capacity of the cars.

STAT

To prevent counterhauling and other inefficient hauls of ferrous metals, an interchange arrangement of equivalent metals has been worked out among enterprises of diffent ministries located near each other.

Efficient Hauling

In order to efficiently haul and to decrease the length of haul of ferrous metals by the railroads and to improve the practice of planning sales and hauling, the long-range development of the specialization of rolling mills and an improvement in the geographical distribution of the metallurgical production in the various economic regions of the country is of decisive importance at present. This makes it possible to eliminate in the metal-producing and metal-consuming regions the existing gap between the consumption and production of metal of various sizes and to relieve the railroads of the inefficient hauling of ferrous metals.

At present, because of complications in connection with the rapid restoration of the national economy, the distribution of rolled products with reference to shapes and sizes does not always correspond to the consuming regions. This leads to inefficient hauling of ferrous metals by the railroads. For example, Uzbek and Kazakh metallergical plants produce metal which is not completely consumed in regions of Central Asia. As a result, metal is sent from the Karaganda and Tashkent Railroad Systems beyond the borders of Central Asia. In 1948, about 50,000 tons of metal were exported from the plants of Cental Asia to various regions of the country.

There is also the counterhauling of metal of different shapes and types between the Donets Basin and the Urals. Until 1949, due to the absence of rolling mills which could have rolled beams No 27 and girders No 26 at plants in the Urals and in Siberia, these troes were shipped to the Urals and Siberia from the plants in the South, a distance of 2,600-4,000 kilometers. Rail tie plates, rolled at the Kuznetsk Metallurgical Combine and finished at the Makeyevka Metallurgical Plant, are delivered to the railroads of the Urals and Siberia with the length of haul of up to 2,600 kilometers. Railroad car wheel tires, produced at the Plant imeni Dzershinskiy in the Donets Basin, are delivered to railroads in the Urals. On the return trip and in approximately the same quantity, locomotive wheel tires, produced in the Novo Tagil'skiy Metallurgical Plant, are hauled a distance of 2,500 kilometers.

In addition, there is also counterhauling of semifinished metal products and rolled products manufactured from these same semifinished products. For example, a number of rolled products have been hauled to Leningrad, although, at the same time, high-quality rolled products are shipped from Leningrad.

In the near future great emphasis will be placed on reducing the hauling of metals between the regions of the South and the Donets Basin. Metallurgical plants of the South and Center, in keeping with their restoration and development, will supply rolled products of all types mainly to consumers located in regions west of the Volga River. Metallurgical plants of the Urals will mainly supply consumers located east of the Volga River as far as Omsk and including the regions of Central Asia. Siberian and Far Eastern plants will supply their respective areas.

The development of specialization of rolling mills, worked out by the government in order to satisfy the consumers of the respective regions, makes it possible to eliminate long hauling of ferrous metals by the railroads.
